

# Error handling

Each API response contains a `success` (boolean) field. When `success` is `false`, the `error` (string) field with the error description is also included.

Example success response:

```
{
  "success": true
}
```

Example error response:

```
{
  "success": false,
  "error": "Missing data"
}
```

In addition, various HTTP errors may occur, e.g. `404` if the endpoint does not exist or `500` if API is unavailable due to some backend malfunction. If the status is not `200`, the contents of response body is unpredictable and should be ignored.
